## 4 Future Research...

# Internet of Things

- Providing internet connectivity to all sort of devices: everyday items, machines, clothing, buildings, ..., in order to collect information on entities and environments. And realize applications;
- Interoperability issues: vertical silos;
- Breaking fragmentation means creating a bridge at some level of ISO-OSI stack;

# Breaking fragmentation

## OSI 7 Layer

# Breaking fragmentation

Let us just consider Application layer protocols, like MQTT and AMQP. The *topic* communication implies that there is an agreement on the semantics among application:

- ① The topic URI is interpreted in the same way;  
*this is the place in which temperature information should be stored*

# Breaking fragmentation

Let us just consider Application layer protocols, like MQTT and AMQP. The *topic* communication implies that there is an agreement on the semantics among application:

- ① The topic URI is interpreted in the same way;  
*this is the place in which temperature information should be stored*
- ② The exchanged information has the same format;  
*information should be provided as a JSON file compliant with a specific JSONSchema*

# Breaking fragmentation

Let us just consider Application layer protocols, like MQTT and AMQP. The *topic* communication implies that there is an agreement on the semantics among application:

- 1 The topic URI is interpreted in the same way;  
*this is the place in which temperature information should be stored*
- 2 The exchanged information has the same format;  
*information should be provided as a JSON file compliant with a specific JSONSchema*
- 3 The exchanged information has the same semantics;  
*no misunderstanding is possible on the meaning of the received value:*  
*mouse* means ‘’ for all participants, and is never intended as ‘’

# Breaking fragmentation

But how do we agree on all this, if applications are developed in different places, different times, by different people, with different purposes?

The Resource Description Framework (RDF) can enrich with semantics all the Application and Information level of the IoT.

# Semantic Internet of Things

# What's a *Thing*?

## IEEE definition

*The Thing is any physical object **relevant** from a user or application perspective.*

# What's a *Thing*?

## IEEE definition

*The Thing is any physical object **relevant** from a user or application perspective.*

## W3C definition

*Things can be **virtual representations** of physical or abstract entities. They can be connected or not connected. Each thing can have one or more virtual representations. Things can have histories, and have identities, rich **descriptions**, services, access control and data handling policies. They have URLs.*

Ref. [1]

# Internet of Musical Things (IoMusT) Ontology

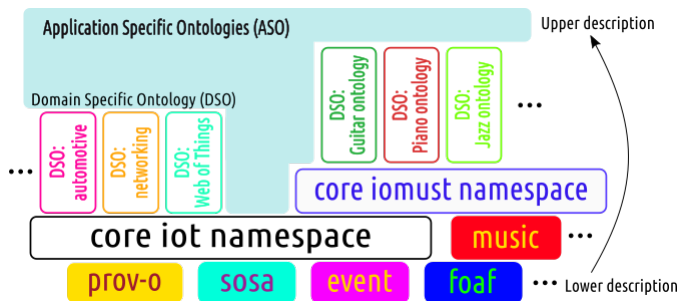

IEEE approach

The Internet of Musical Things is the ensemble of interfaces, protocols and representations of music-related information that enable services and applications serving a musical purpose based on interactions between humans and Musical Things or between Musical Things themselves, in physical and/or digital realms.

Music-related information refers to data sensed and processed by a Musical Thing, and/or exchanged with a human or with another Musical Thing [2].

# Internet of Musical Things (IoMusT) Ontology

IEEE approach

- Is IoMusT a subcase of IoT?
- It presents an approach, a model to realize a semantic and fully interoperable IoT connecting different fields incrementally;
- Topic completely unexplored in literature: music+IoT+semantics [3];

	ns:Bob	ns:Wardrobe	ns:SmartCar	ns:Violin	ns:SmartViolin	ns:TShirt	ns:StageLight	ns:VR_HeadSet	ns:HeartBeatSensor for music experiment

iomust:WearableMusicalThing									✓

## Rule Example 1 (not reversible!)

`?s a iot:Thing, mo:Instrument`  $\Rightarrow$  `?s a iomust:MusicalThing`

Where the Musical Thing is *a thing used to produce or enjoy music, with reference to its context.*

## Rule Example 1 (not reversible!)

`?s a iot:Thing, mo:Instrument`  $\Rightarrow$  `?s a iomust:MusicalThing`

Where the Musical Thing is *a thing used to produce or enjoy music, with reference to its context*.

## Rule Example 2

`?e co:elementOf ?s; a iomust:MusicalThing. ?s a co:collection`  
 $\Leftrightarrow$  `?s a iomust:StageEquipment`

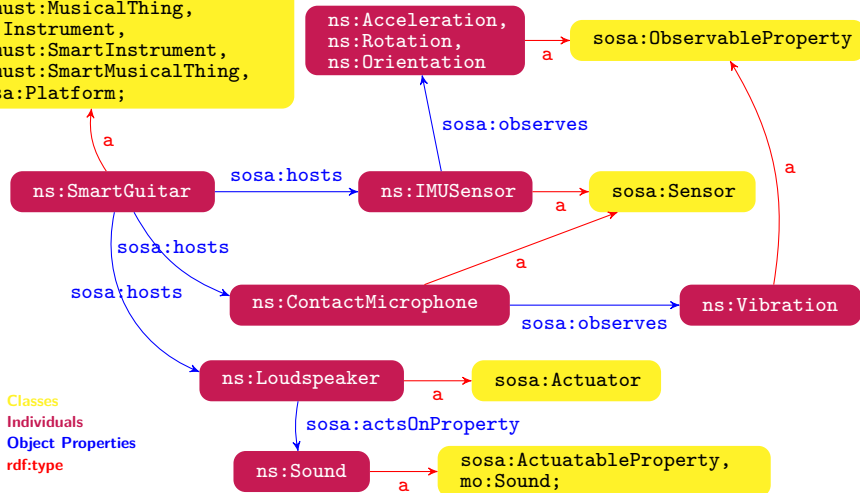

# IoMusT Ontology example I

How do we describe a Smart Guitar with:

- ① An IMU sensor unit;
- ② A contact microphone;
- ③ A loudspeaker;

# IoMusT Ontology example I

```
iot:Thing, iot:SmartThing,  
iomust:MusicalThing,  
mo:Instrument,  
iomust:SmartInstrument,  
iomust:SmartMusicalThing,  
sosa:Platform;
```

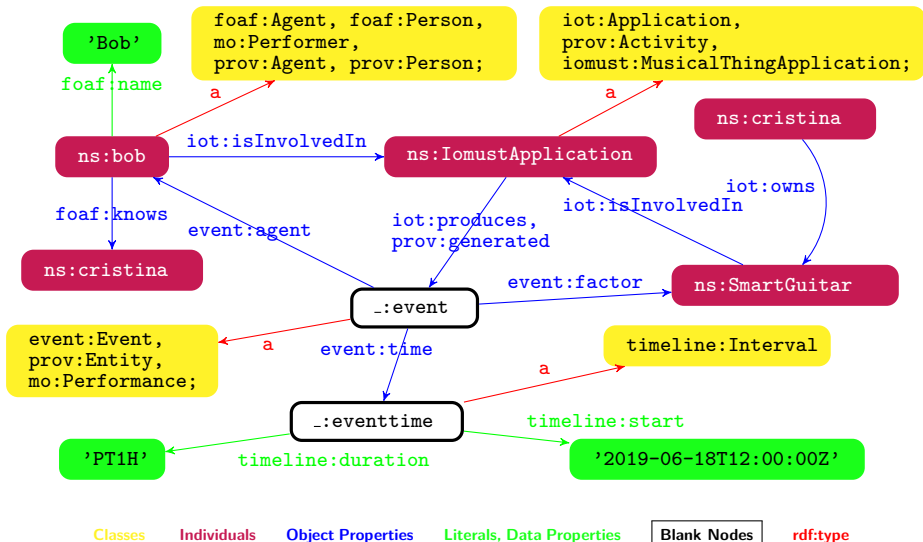

# IoMusT Ontology example II

How do we describe an IoMusT application:

- ① A music performance made by someone;
- ② Using a Smart guitar belonging to someone;
- ③ Starting at a specific time;
- ④ Having a specific duration;

# AudioCommons project I

## SEPA usage example

# AudioCommons project II

## SEPA usage example

Ref. [5, 6, 7]

# Web of Things I

## Prerequisite

The Web of Things was introduced approximately in 2010 [8]. The fragmentation of IoT was addressed considering that

- the hardware available today is cheap and powerful;
- the World Wide Web stack, including HTTP protocol and JSON format for data exchange are broadly used;
- the RESTful design can be applied also to IoT systems and giving a broader meaning to the term 'resource'

# Web of Things II

## Prerequisite

As discussed, the W3C provided its own definition of Thing, highlighting the fact that **they have URIs**.

The W3C WoT Working Group was created in this context to develop an interaction model and a common vocabulary to identify the Thing capabilities in the environment.

This Thesis work takes inspiration from the W3C drafts, and combines it with the aforementioned SEPA architecture [9].

# Comparison: W3C WoT vs SWoT ontology tools

W3C WoT	SWoT (this work)
Devices have their <b>Thing Descriptions</b> (TD). They provide it as small web servers, in JSON-LD;	Devices post their TDs as a graph into SEPA;
Clients still have to discover the devices by their own means, or discovery repos have to be implemented;	SEPA provides natively semantic discovery over the RDF graph of TDs;
Direct interaction after interpreting the TD;	SEPA-mediated interaction according to the SWoT dynamic ontology
Reduced data model;	Extended data model and protocol;
No shared context, since TDs are separate universes;	SEPA may contain a shared context subgraph, depending on applications;

## Abstract

`https://fr4ncidir.github.io/SemanticWoT/`

# Programming the SWoT

A Python3 framework was developed to fully exploit the SWOT ontology presented, based on a SEPA engine:

- 1 semantic TD definition and posting;

All this by using SEPA's engine with SPARQL 1.1 Queries, Updates and Discoveries.

A Python3 framework was developed to fully exploit the SWOT ontology presented, based on a SEPA engine:

- ① semantic TD definition and posting;
- ② event subscription and notification;

All this by using SEPA's engine with SPARQL 1.1 Queries, Updates and Discoveries.

A Python3 framework was developed to fully exploit the SWOT ontology presented, based on a SEPA engine:

- ① semantic TD definition and posting;
- ② event subscription and notification;
- ③ action request and execution;

All this by using SEPA's engine with SPARQL 1.1 Queries, Updates and Discoveries.

A Python3 framework was developed to fully exploit the SWOT ontology presented, based on a SEPA engine:

- ① semantic TD definition and posting;
- ② event subscription and notification;
- ③ action request and execution;
- ④ full semantic discovery;

All this by using SEPA's engine with SPARQL 1.1 Queries, Updates and Discoveries.
